Este Número dos Cadernos Sociedade e Trabalho retoma a publicação de materiais elaborados a partir da exploração da Base de Dados dos Quadros de Pessoal. Trata-se de um conjunto de artigos preparados tendo por base comunicações apresentadas no *Workshop* organizado pelo Núcleo de Investigação de Políticas Económicas da Universidade do Minho e no qual participaram investigadores/académicos ligados a diversas universidades portuguesas e de outros Estados-Membros da União Europeia.

A Base de Dados dos Quadros de Pessoal, sob coordenação institucional e técnica do Gabinete de Estratégia e Planeamento do MTSS, organiza de forma regular informação estatística para o conhecimento da estrutura do tecido empresarial e dos atributos e funcionamento do mercado de emprego. A qualidade e robustez técnico-científica desta informação é reconhecida pela comunidade académica a nível nacional e internacional e tem alimentado projectos de investigação e pesquisa empírica, com presença frequente em publicações de análise económica.

O aprofundamento do trabalho técnico do GEP/MTSS tem permitido consolidar esses níveis de qualidade, nomeadamente com a estruturação do Sistema de Informação Longitudinal de Empresas, Estabelecimentos e Trabalhadores (SILEET), uma base que integra dados dos Quadros de Pessoal desde 1982 até 2007.

A informação disponível neste Sistema destina-se a utilizadores que pretendam efectuar estudos sobre trajectórias de empresas, estabelecimentos e trabalhadores (p.e., mobilidade geográfica, profissional e salarial). Os ficheiros existentes permitem, ainda, ligações com outras fontes administrativas externas autorizadas.

Abstract | From 1985 to 2007, by applying to the *Quadros de Pessoal* dataset the methodology and definitions of the OECD/Eurostat Manual on Business Demography Statistics. We observe that firm size has been decreasing in Portugal over all broad sectors, regions and entrants and exiters from the market and also that firm size distribution is right-skewed, evolving over time towards a lognormal distribution.

1 The opinions and analysis in this work are the sole responsibility of the authors. The authors would like to thank Gabinete de Estratégia e Planeamento of the Portuguese Ministry of Labour and Social Security for the provision of data and the helpful assistance.

1. Introduction

Firm size distribution has always drawn a great deal of attention in Portugal, often related to the so-called lack of performance and competitiveness, in comparison to bigger sized international firms², due to the overall small dimension of the internal market (especially for nontradeables) and to the country's type of specialisation model. In fact during the last decades, there has been an increasing number of smaller sized enterprises and a decrease of firm size across all main sectors, for both observed entrants and exiters in the market.

The increasing predominance of small firms in the total enterprise population is not unique to Portugal, it is a phenomena shared by other countries (Eurostat, 2009; OECD, 2008; Núñez, 2004; Consejo Superior de Cámaras de Comercio, Industria y Navegación de España, 2003; Cabral, 2007; Bartelsman et al., 2005a). There is a great amount of evidence in other developed economies, of the shift in the firm size distribution towards small production units since the 1970s, after years of dominance of the economies of scale in production. Why this change has taken place is not so clear, though. From a theoretical point of view, there is not a single theory of the firm that is able to fully explain the reasons for optimal firm size change. Different theories are then put forward, by different authors that incorporate one or several possible approaches (You, 1995). It most probably is a consequence of the combination of a whole set of factors which concern both specialisation effects and within sector effects, which differ according to the specificities of the country or sector of activity considered. Still, we are able to frame this phenomenon into three main dimensions. The first, is the result of the combination of an intensified global competition (mostly from Asian countries and Eastern Europe, which has been responsible for successive waves of downsizings over the last years) with the acceleration of technological change, which has

2 "It is often said there are too many small firms in Portugal, and that average firm size is too small" (Cabral, 2007).

contributed to the reduction of the minimum scale of entry³. The second is the increase in the degree of uncertainty, triggered by episodes of oil price shocks and price instability in raw material markets. Some authors claim that this might have impacted the mass production system directly, thus promoting smaller scale and more flexible production units, where smaller firms develop a comparative advantage relatively to their larger counterparts. Thirdly, the increased globalisation and the digital economy revolution, which shifted comparative advantages towards knowledge-based economic activities, where the individual is at the centre of the knowledge chain, as opposed to the firm⁴.

This work consists on the application of the methodology and definitions comprehended in the Manual on Business Demography Statistics (OECD/Eurostat, 2007) to the *Quadros de Pessoal* dataset (Employment Administrative Records by the Portuguese Ministry of Labour and Social Security). Accordingly, the analysis focuses on a specific subsample of *Quadros de Pessoal*, consisting only of the population of active enterprises⁵ with at least one paid employee. This is the so-called employer enterprise population⁶.

The next section describes the main patterns of firm size evolution in Portugal over the last 22 years, section 3 looks at the decomposition of firm size into specialisation and within sector effects, section 4 highlights the importance of employment creation by small firms, section 5 approaches the issue of firm size distribution over time and broad sectors, and finally, section 6 concludes.

2. Patterns of Firm Size Evolution in Portugal

The size of the small business sector in a country is often used as a proxy for entrepreneurial activity. The number of enterprises by size class (Figure 1) highlights the growing importance of small and medium (SME) sized enterprises in Portugal, which are considered a key source of dynamism and innovation in developed and emerging economies, thus making important contributions to job creation, economic growth and productivity (OECD, 2005).

- 3 Firms prefer to enter small, so as to incur in minimum costs, in case they are forced to exit the market.
- 4 This can lead to situations where individuals who have acquired a specific technological knowledge, leave the incumbent firm to create his or her own new firm, where this knowledge starts being commercialised.
- 5 An enterprise, according to the Eurostat/OECD Manual (2007) is the "smallest combination of legal units that is an organisational unit producing goods or services, which benefits from a certain degree of autonomy in decision-making, especially for the allocation of its current resources". An enterprise carries out one or more activities at one or more locations and may be a sole legal unit.
- 6 The OECD, the Eurostat and the EU member states have agreed that the collection of data on enterprises that have paid employment can improve the compatibility of enterprise birth and death rates among all OECD countries and some EU countries (Eurostat/OECD, 2007). This data is intended to be consistent and to complement other methodological guidelines

In most countries, firms with less than ten employees represent around three quarters of the employer enterprise total population. Portugal does not seem to be an outlier, as the population of firms is dominated by small and micro units in a wide range of countries (Eurostat, 2009⁷; Bartelsman *et al.*, 2005b; Bartelsman *et al.*, 2004).

In Portugal, the number of active employer enterprises with fewer than 5 employees (micro-firms) went over the 200.000 threshold after 2004 (Table A.1 in Annex), but they already represented a significant share of the employer enterprise universe. Since 1996, more than 60 % of all employer enterprise firms in Portugal are micro firms, and more than 81 % have fewer than 10 employees. Small firms, with less than 10 employees, tend to increase its share in the total population, throughout all the observed period (74 % in 1986, 82 % in 1997 and 85 % in 2007). In 2007, 97,8 % of the Portuguese enterprises present in our dataset employed less than 50 workers, compared to 95 % in 1985.

Figure 1 Population of Active Employer Enterprise Population, by Size Class (in Thousand Enterprises and %)

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

- 7 According to Eurostat (2009), "there is an obvious tendency for enterprises to start very small". In 7 of the considered countries in figure 2, more than 50 % of newly born enterprises have between 1 and 4 paid employees. This size class combined with the enterprises with no paid

The increasing presence of small firms in Portugal is considerable and visible throughout all broad economic sectors, both in terms of the number of enterprises and the number of employees (Table 1). During the period of 1995 to 2007, 92,5 % of total enterprises in the economy employed fewer than 20 workers and all sectors, except for manufacturing (81,5 %), have a share of over 90 %. From the first (1995-1999) to the second sub-period (2000-2007), the number of small enterprises rises in all sectors, but manufacturing displays the highest increase in this size class, above the total economy's, indicating a faster reduction in enterprise size.

On the other hand, the employment share of small firms is much lower, as already verified for other countries (Bartelsman *et al.*, 2005a). This stylised fact, whereby small enterprises constitute the vast majority of firms, but account for proportionally less employment, is common in the literature and is also verified for this universe of employer enterprises.

In parallel to the evolution of the number of enterprises, employment also shows a tendency to rise in all sectors of activity of this size class, except for services. This trend is not only influenced by the level of economic activity⁸, but also by the industry structure, as an economy with a large service sector such as Portugal (Table A.2), is more likely to have a higher share of small enterprises in total employment (Table 8).

Table 1 Share of Enterprises with Fewer than 20 Employees, in the total Population of Firms and in Total Employment⁹
(Enterprises with Fewer than 20 Employees as a % of Sector's Total)

	Enterprises					Employment				
	Total economy	Agriculture and Fishing	Manufacturing	Services	Construction	Total economy	Agriculture and Fishing	Manufacturing	Services	Construction
1995-2007	92,5 %	95,5 %	81,5 %	94,7 %	92,9 %	39,1 %	67,2 %	25,1 %	42,9 %	52,1 %
1995-1999	91,5 %	95,6 %	79,6 %	94,6 %	92,2 %	36,6 %	61,7 %	22,5 %	43,8 %	46,5 %
2000-2007	92,9 %	96,9 %	82,6 %	94,8 %	93,1 %	40,4 %	70,0 %	26,8 %	42,5 %	54,4 %

Source: Own calculations based on Quadros de Pessoal, GEP, MTSS.

By combining the regional with the size class dimension, we may also observe the predominance of small firms in most regions at the NUT II level (Tables 2 and 3), in

8 We have found that the economic cycle highly correlates with enterprise births and deaths cycles. In different regression models we have found that GDP is consistently a statistically significant variable.

9 Sections A to P of the Classification of Economic Activities (CAE) Rev. 2.1. were considered for

particular in the Algarve¹⁰, the Açores and the Alentejo. Since 1995, all regions display a similar trend of increasing share of firms with fewer than 20 employees and of employment, except for Alentejo and Açores (from 1995 to 2007).

Table 2 Share of Active Employer Enterprises with Fewer than 20 Employees in Total Number of Enterprises by NUT II Region (%)

10 Even when firms with fewer with less than 50 employees are considered, the Algarve and the Alentejo are still the regions with the highest share of small enterprises in 2007.

3. Firm Size Across and Within Sectors

The decrease in firm size reflects the influence of both specialisation effects and within sector effects in the economy. Concerning the former, we observe that more small enterprises are born in Portugal each year, in particular in the service sector (Table A.3.), which holds a lower average firm size than the manufacturing sector (Table A.5.). By comparing different time frames across size classes, we also observe that firm rotation decreases with size¹¹. More firms are born within the 1-4 size class (77,9 % share of total enterprises in 1987-2000 compared to 80,3 % in 1989-2007) and firms with fewer than 20 employees have also been increasing over the past decades (Table 4).

Table 4 Average Employer Enterprise Births¹² by Periods and Firm Size

Period	Average enterprise births	Cumulative by Size Class (n.º employees)					
		1 - 4	1 - 9	1 - 19	1-49	1 - 249	ALL
1987-2000	31.368	24.442	28.900	30.476	31.147	31.347	31.368
% of total	100	77,9	92,1	97,2	99,3	99,9	100,0
1987-2007	36.803	29.555	34.256	35.885	36.574	36.781	36.803
% of total	100	80,3	93,1	97,5	99,4	99,9	100,0
1992-1999	33.383	26.483	30.982	32.511	33.162	33.363	33.383
% of total	100	79,3	92,8	97,4	99,3	99,9	100,0

% of total	100	83,5	94,4	98,0	99,5	99,9	100,0

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

On the other hand, there has been an overall decrease in within sector's average size, for all broad sectors of the economy, and particularly for manufacturing (Table 5). While the average size of manufacturing firms still is at least twice as large than services¹³ (Table A.2.), it tends to decrease faster between the two

11 This is also visible for employer enterprise deaths and naturally for churn rates.

12 According to the OECD, the core measure of births reflects the concept of employer enterprise birth. A birth amounts to the "creation of a combination of production factors with the restriction that no other enterprises are involved in the event" (Eurostat/OECD, 2007). Births do not include entries into the population which result from break-ups, spit-offs, mergers, restructuring of enterprises or reactivations of units which are dormant within a period of two years. This population thus consists of enterprises that have at least one paid employee in its birth year and also of enterprises that, despite existing before the year in consideration, were below the one employee threshold. An employer enterprise entry is thus counted in the dataset as a birth of an employer enterprise after it recruits its first employee, while complying with the above mentioned requisites.

13 A known stylised fact is that there is a substantial sectoral component in firms size and that manufacturing firms tend to be larger than services firms (Bartelsman *et al.*, 2005a).

sub-periods than the remaining sectors (from 20,8 average employees before 2000, to 17,4 afterwards)¹⁴.

Table 5 Average Firm Size by Broad Sectors and Periods (Number of Employees)

	Total economy	Agriculture and Fishing	Manufacturing	Services	Construction
1995-2007	10,0	4,9	18,9	8,4	8,9
1995-2000	10,9	5,5	20,8	8,6	9,5
2000-2007	9,4	4,5	17,4	8,3	8,3

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

Moreover, the average number of employees across all main sectors has decreased, for both observed entrants and exiters in the market. Entrants and exiters are on average of smaller size than incumbent firms (ranging from 35 % to 45 % for entrant's size and 39 % to 50 % for exiters, over the period). A typical entrant is smaller than the industry average¹⁵, and the difference in size compared to the incumbent has been closing down in all the sub-periods considered (Table 6).

Table 6 Average Number of Employees per Firm

Period	Total economy	Entrants	Exiters
1987-2007	11,9	4,6	
1987-2000	13,2	5,0	5,8
2000-2005	9,5	4,0	4,2
1985-2005	12,8		5,5
1985-2000	13,9		5,9
2000-2007	9,4	3,9	

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

In Portugal, entrants size is less than half of the economy's average size, in line with the results obtained for other developed countries (Cabral, 2007; Bartelsman *et al.*, 2005b; López-García and Puente, 2006) for all the observed periods,

14 Bartelsman *et al.* (2005a) divides firm's size across countries and places Portugal in the group of the largest sized countries (US, France and Germany) where the average size is of 15 employees in the total business sector. They obtain an average of 16,8 employees per firm in Portugal for the period 1989-1994. Although we obtain different averages, we also observe that average firm size in services is clearly below the economy's average and that the ratio of manufacturing firm size relative to total economy is 1,8, the same obtained by Bartelsman *et al.* (2005a).

15 The fact that the new entrant's size is smaller than incumbents is common to many countries (Bartelsman, 2005a; Nuñez, 2004; Cabral, 2007). It is often related to learning models that approach entrepreneurship dynamics as a learning process, where firms enter the market with a smaller size due to the uncertainty about its potential profitability.

exception made for the Agriculture and Fishing sector and for the Construction sector after 200. Still, according to Cabral (2005), Portugal has one of the lowest ratios of entrant and exiter size with respect to total average size.

In order to properly assess the contribution of the sectoral specialisation versus the within sector to the trend of decreasing average firm size, we follow a decomposition¹⁶ inspired by Bartelsman *et al.* (2005a) and Bartelsman *et al.* (2004). In our analysis, the decomposition of average firm size is measured against the 1995 benchmark, in order to understand how much of the deviation in average firm size can be accrued to the fact that Portugal is specialised in sectors that display specific characteristics which impact in firm size and how much can be accrued to the within sectors discrepancies in average size.

Table 7 Shift Share Analysis of the Determinants of Firm Size (Benchmark year = 1995)

	Contribution coming from differences in:			Total
	Sectoral composition	Average size of firms	Interaction between composition and size	
1996	0,02	-0,3	-0,04	-0,32
1997	0,05	-0,59	-0,09	-0,63
1998	0,26	-0,37	-0,14	-0,25
1999	0,11	-0,87	-0,21	-0,98
2000	0,11	-1,34	-0,36	-1,59
2001	0,23	-1,32	-0,5	-1,59
2002	0,81	-1,87	-0,49	-1,55
2003	-0,21	-1,95	-0,18	-2,34
2004	-0,31	-1,98	-0,7	-2,36
2005	-0,2	-2,23	-0,27	-2,71
2006	-0,2	-2,21	-0,2	-2,62

Source: Own calculations based on Quadros de Pessoa, GEP, MTSS. Note: Done at a two digit level of the Classification of Economic Activities Rev. 2.1.

16 This decomposition exploits the difference between the mean in a given year and a benchmark mean. The formula considers an expression where S_{95} is the annual average firm size for the total economy, and S_t is the overall total economy average in 1995, considered as the benchmark year. Thus, the difference between the benchmark year and the overall mean in a given year, can be decomposed as follows:

$$s_t - s_{95} = \sum_i \alpha_i^t s_i^t - \sum_i \alpha_i^{95} s_{95}^i = \sum_i (\alpha_i^t - \alpha_i^{95}) \bar{s}_{95}^i + \sum_i (s_i^t - s_{95}^i) \bar{\alpha}_{95}^i + \sum_i (s_i^t - s_{95}^i) (\alpha_i^t - \alpha_i^{95})$$

$$= \Delta_\alpha + \Delta_s + \Delta_{\alpha s}$$

Where Δ_α accounts for the sectoral composition, Δ_s for the differences within sectors and $\Delta_{\alpha s}$ for the relationship between size and sectoral composition, similar to a covariance measure. A positive term means that size and sectoral composition deviate from the 1995 benchmark in the same direction.

In the expression, $\sum_i \alpha_i^t s_i^t$, s_i^t is the average firm size of sub-sector i at the 2 digit level of the Classification of Economic Activities Rev. 2.1. in year t and α_i^t is the share of firms in sub-sector i of employer enterprises in the economy in year t .

Our findings show that the within sector effect plays a more important role in explaining differences in firm size across the period 1995-2006, as the absolute value of its composition term is greater in absolute value than that from the sectoral composition, and this effect is more expressive over time (Table 7). Even controlling for sectoral specialisation, intrinsic characteristics of sectors are a fundamental determinant of size structure. This can also indicate that the same sectors can be characterised by different and evolving size structures over time¹⁷. The interaction term points to a somehow volatile correlation between the two terms, indicating that possibly no strong correlation exists as the interaction term stays negative, despite the signal change of the sectoral composition term after 2003¹⁸. The total component values indicate that overall firm size has been decreasing over time. The year of 2006 points to a stabilization in the evolution of all the components.

Bartelsman *et al.* (2004 and 2005a) and Pagano and Schivardi (2003) have done a within sector comparison of size differences between different countries, observing that the overall differences in average firm size between countries do not solely reflect specialisation differences, but rather variations in size within sectors. The most important finding of the industry decomposition for the manufacturing sector, undertaken by Bartelsman *et al.* (2005a), is that the within sector differences play the most important role in explaining differences in size across countries. This component is much larger than the one of sectoral composition for almost all countries, including Portugal. In Bartelsman *et al.* (2004), those conclusions are again underlined, but the overall sectoral composition now seems to play a more relevant role in countries such as Portugal, Denmark and France. The interaction terms are correlated positively in both studies, indicating a possible link between size structure and sectoral specialisation, which is not found in our calculations.

4. Employment Creation

There is considerable policy interest in the way in which enterprises grow and create employment, particularly for small firms, which play a key role in labour

17 Firm size, summarised by average size and dispersion have an important sectoral component. The sectors with the largest standard deviation are "Electricity, gas and water supply" because of its heavily regulation and legal monopolies and "Financial activities" and "Public Administration, Defence and Social Security", "Fishing" and "Education". These are also the sectors with the average highest size. The less dispersed is "Gross and retail commerce" and "Hotels and restaurants". Manufacturing standard deviation is twice as large as total deviation, in line with other countries (Bartelsman *et al.*, 2005a).

When the coefficient of variation is used, the dispersion is highly reduced, with most sectors presenting a higher coefficient of variation than the country's average.

18 The fact that sectoral composition becomes negative from 2003 might have been influenced by the construction sector that, which lived through an expansion period, both in terms of share of enterprises and employment before 2000, showing a marked decline after 2003 in terms of enterprises and employment share, and average size.

creation and reallocation. If a country's environment tends to favour small sized firms, this should induce a proportional higher employment share in sectors where technological factors favour small size (Pagano and Schivardi, 2000).

In Portugal, the important contribution to aggregate employment growth of the smallest size classes is sustained by the outstanding employment performance of new firms (Figure A.1.), as well as by the amount of employment creation of small established firms. Over the whole period 1987-2005, firms with fewer than 20 employees created 2.828.287 jobs (65,7 % of total) and are responsible for almost a quarter (23,4 %) of all job creation in the dataset from 1987-2005 (Table 8). The annual net rate of labour allocation of these firms has been positive since 1987, which means small firms create more jobs than they destroy, even in periods of economic downturn.

Table 8 Employment Creation from 1987 to 2005, by Size Class

1987-2005	Total employment creation	Employment creation by entries	Employment destruction by exits	Net job gains by existing firms	Percentage created by firm rotation	Percentage created by existing firms
	1	2	3	4=1-2+3	5=-(4-1)/1*100	6=4/1*100
1 to 4	1.401.816	1.068.780	704.531	1.037.567	26,0	74,0
5 to 9	818.107	575.004	378.679	621.782	24,0	76,0
10 to 19	608.364	414.043	312.102	506.423	16,8	83,2
20 to 49	590.713	386.045	340.473	545.141	7,7	92,3
50 to 249	539.847	363.199	387.057	563.705	-4,4	104,4
250 or more	342.969	317.208	307.236	332.997	2,9	97,1
Total	4.301.816	3.124.279	2.430.078	3.607.615	16,1	83,9

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

The ratio composed by the annual growth rate of employees over the growth rate of employer enterprises (Table A.4.), shows that while small firms with fewer than 20 employees create a substantial amount of employment, annual enterprise growth is higher than employment's. A ratio below one is also systematically obtained in the service sector from 1995 onwards, where small firms still account for a larger share of employment than in manufacturing, because of the determinant role played by economies of scale and technological factors. This fact also sheds some light on the evolution of firm size towards smaller size classes.

5. Has Firm Size Distribution Changed in Portugal?

Cabral and Mata (2007) reveal that age also plays an important role in the process of shaping firm size distribution. Although a deeper analysis of firm age and firm size would be useful, it is not within the scope of this analysis. We provide

instead an overview of the time series perspective of the data, confirming that average firm size has been markedly decreasing since 1988, for all the observed survival¹⁹ cohorts, from 1 to 5 years of survival (Figure 2). The gap in average firm size between the firms that managed to survive for 1 and 5 years in 1992 (7 and 11 employees, respectively) is higher than that of 2007 (4 and 6 employees, respectively). Over time, there has been a closing of the gap of average firm size between the first and the fifth year of survival, and particularly from the second to third year of survival, indicating that firms that manage to survive longer do not necessarily grow in size.

Figure 2 Average Firm Size of Employer Enterprises by Years of Survival after Birth (Number of Employees)

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

Therefore, an employer enterprise created in 1987, which survived for 5 years, had in 1992 an average 11 employees, compared to an average of 6 employees in 2007, for the same survival period (Figure 3).

¹⁹ According to the Manual of Business Demography Statistics (Eurostat/OECD, 2009), the survival of an enterprise is defined in the following way: "The number of n-year survival enterprises for a particular year (t) refers to the number of enterprises with at least one employee for the first time in year (t-n) which had not died in year (t)." The survival of an enterprise is an event that should always be observed between two consecutive years.

Figure 3 Average Firm Size, 1992 and 2006 Cohorts, Number of Employees (%)

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

Turning to firm size distribution, it is important to keep in mind that this distribution does depend heavily on the type of data source considered (Cabral, 2007). Cabral and Mata (2003)²⁰ tested the hypothesis that more comprehensive data sets (which consider micro data as *Quadros de Pessoal* does) are described by firm size distributions that evolve over time and are skewed to the right, thus being distinct from the lognormal distribution curve²¹. Following the same methodology, we applied a nonparametric estimation method, a gaussian kernel density smoother with a bandwidth of 0,5 to the logarithm of firm size to test if firm size (expressed as the log of the employment of the firm) distribution is stable and approximately lognormal for the population of active enterprises, births and deaths²².

We have found a distribution with a distinct shape from the Normal distribution, confirming Cabral and Mata's (2003) conclusions. Our results also show that firm size distribution is skewed to the right and that the distribution is not stable over time. The whole firm size distribution has indeed been shifting to the smallest size classes both in the service, manufacturing and construction sectors (Figure 4).

20 They also refer that several feature of the Portuguese datasets are consistent with findings from other countries.

21 The lognormal distribution seems to empirically fit well data from commonly used databases and theoretically supports growth rates being independent from firm size.

22 This evidence is not included in the present analysis, but available at request.

Figure 4 Firm Size Distribution in 1985, 1995 and 2007

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

In order to eliminate the possibility of missing out on relevant sector specific effects, we introduce the firm size distribution in the manufacturing and service sector in Annex (Figures A.2. and A.3.).

The visual results are confirmed by the normality test implemented, as described by D'Agostino, Balanger and D'Agostino, Jr. (1990). The D'Agostino's K^2 test allows rejection of the normality, for all the distributions. The firm size distribution is thus positively skewed when compared to the Normal distribution. Again, this pattern of right skewness is not unique to Portugal (Bartlesman *et al.*, 2003; Cabral, 2007).

Considering the evolution of the firm size density distribution, it is also possible to observe that it becomes biased to the left, with smaller rather than larger firms becoming predominant in all broad sectors considered. Throughout time, this process drives the population of employer enterprises to smaller units (Figures A.4., A.5. and A.6.). This conclusion also holds for enterprise births and deaths.

Figure 5 The Cumulative Distribution Function of Firms Size for the Manufacturing, Construction and Services Sectors, 1985 and 2006 Cohorts

Source: Own calculations based on *Quadros de Pessoal*, GEP, MTSS.

6. Final Remarks

Over a period of more than 20 years, we find an overall decreasing average size for employer enterprises in Portugal, which is extended to all broad sectors, NUT II regions, entrants and exiters in the market. Given the growing importance of small enterprises, both in terms of the number of small employer enterprises and their share in employment creation, it is important to address what kind of policy implications should be drawn from the observed dynamics, given that small sized firms are usually the most exposed to specific constraints, such as administrative burdens and financial restrictions.

Abstract | The banking industry, highly regulated in past years and more recently exposed to intense institutional, technological and organisational change, looks particularly suited for appreciating the evolution of internal labour markets (ILMs). Based on Quadros de Pessoal linked employer-employee data (LEED), the paper assesses the existence and the evolution of ILMs in the Portuguese banking industry between 1989 and 2003. By merging QP data with information provided by collective labour agreements, the proposed analysis overcomes the traditional weakness of LEED compared to personnel files, i.e. the poor discrimination between jobs and job grades. The examined data show that the labour markets of large Portuguese banks reproduce some characteristics of standard ILMs, including privileged recruitment at ports of entry, substantial opportunities of internal vertical and horizontal careers, and lower bounds of wage ranges attached to job hierarchy. However, the observed companies are ready to turn to competitive mechanisms to overcome the internal shortage of crucial human resources or to cut the cost of non firm-specific human capital.
